

**BMS(Modbus) Protocol (V1.2) for Gree  
Multi VRF System(CAN Mode)**

**GREE ELECTRIC APPLIANCES, INC. OF ZHUHAI**

Thanks for your purchase of the long-distance monitoring Modbus Gateway of GREE Center air conditioners. In order to seamlessly interface it to the Building Management System (BMS), please read this manual carefully before installation and use and keep it in a handy place for future reference.

## Preface

This protocol specifies the communication format and also the data format for the communication of the multi VRF system.

This protocol is applicable to the Multi VRF System(CAN Mode).

Please pay particular attention to the following three points before the development of the BMS software.

- 1) Make sure you have read the section 6 “*Precautions before the Use of the Communication Module*”.
- 2) Make sure you have read all parts which are about the precautions before the development to the BMS interface of each unit, like 5.1.2 “*Precautions before the Development to the BMS Interface of Multi VRF System(CAN Mode)*”
- 3) Please contact GREE technicians to confirm the compatibility of the BMS system.

## **1. Terms and Definitions**

### **1.1 Modbus Communication**

Modbus protocol is such a protocol as is used for industrial communication and distributed control system. Modbus network is a master-slave network, allowable for the communication between one master unit and multiple slave units through data interchange. The Modbus communication is realized in the request-response way, that is, each request sent by the master unit is corresponding to a response replied by the slave unit.

### **1.2 ASCII Mode**

Under this mode, as for the communication via the Modbus, eight bits in one piece of information can be transmitted as two ASCII characters.

### **1.3 RTU Mode**

Under this mode, eight bits can be divided into two four-bit hexadecimal characters. The advantage of the RTU mode is that with the same baud rate the transmitted character density is higher than that in the ASCII mode. Each piece of information should be transmitted continuously.

### **1.4 Master Unit**

It indicates the device which sends out the request to Modbus, like a PC.

### **1.5 Slave Unit**

It indicates such a device as is capable of responding to the request sent by the master unit, like a Modbus Gateway which is taken as an example in this protocol.

### **1.6 Coil**

It is expressed by one bit, like the switch bit, failure bit etc. The coil is a universal express way of the Modbus protocol and actually it is a one-bit data value, namely Boolean, switching value.

### **1.7 Register**

It is expressed by two bytes (16 bits), like temperature, mode etc. The register is a universal express way of the Modbus protocol and actually it is a word (16 bits), or an analog value.

### **1.8 Device Address**

It indicates the address of the Modbus Gateway, through which the master unit can identify each Modbus Gateway in the network. Address range: 1~255. "0" is the address of the broadcast (it can be received by all Modbus Gateways).

### **1.9 Broadcast**

When the master unit sends out a control frame, then all slave units in the network can receive it and then all perform this control action (but no reply is given). The device address for the broadcast frame is 0

### **1.10 Function Code**

It is used to identify the function of the communication frame. See the following table for the function codes covered in this protocol.

Table 1 Function Code

| Description              | Function Code |
|--------------------------|---------------|
| Read Multiple Coils      | 0x01          |
| Read Multiple Registers  | 0x03          |
| Write Multiple Coils     | 0x0f          |
| Write Multiple Registers | 0x10          |

### 1.11 Starting Address

It indicates the starting address of the register (coil: bit address; register: word address). The data translation starts from the high-order eight bits to the low-order eight bits.

### 1.12 Data Size

It indicates the operated data count starting from the starting address (coil: bit count, register: word count). The data translation starts from the high-order eight bits to the low-order eight bits.

### 1.13 Byte Count

It indicates the count of the effective bytes during the data transmission.

### 1.14 Effective Data

It indicates the control data, status data etc.

### 1.15 Alarm Code

It indicates the error type which is detected by the Modbus Gateway when the master unit is sending the request frame.

### 1.16 CRC

It indicates the cyclic redundancy code consisting of two bytes. The data translation starts from the low eight bits to the high-order eight bits. See Annex A for more details of its calculation.

### 1.17 Request Frame

It is the request sent by the master unit to the Modbus Gateway.

### 1.18 Response Frame

It is the response replied by the Modbus Gateway to the request frame sent by the master unit.

### 1.19 Communication Frame

It is the collection of continuously transmitted bytes during the communication.

### 1.20 BMS

Its full name is building management system

## 2. Brief Introduction to the BMS System

1) The Modbus monitoring system is capable of controlling more than 256 sets of outdoor units and 1024 indoor units at the same time.

2) The interface RS485 of Modbus communication protocol, provided by the long-distance monitoring system, can be directly connected with the BMS system or Gree long-distance monitoring system, that is, control more than 256 sets of outdoor units and 1024 indoor units and display their running status at the same time. The control function of the BMS system is equal to that of the long-distance monitoring system. However, the command sent later takes the priority.

## 3. Network Topology

### 3.1. General

1) As shown in Fig. 1, it can be seen that the whole network consists of two parts: units network and Modbus network, which are connected through the Modbus Gateway by which the communication data can be interchanged.

### 3.2. Topological Structure

Fig.1: Topological Structure

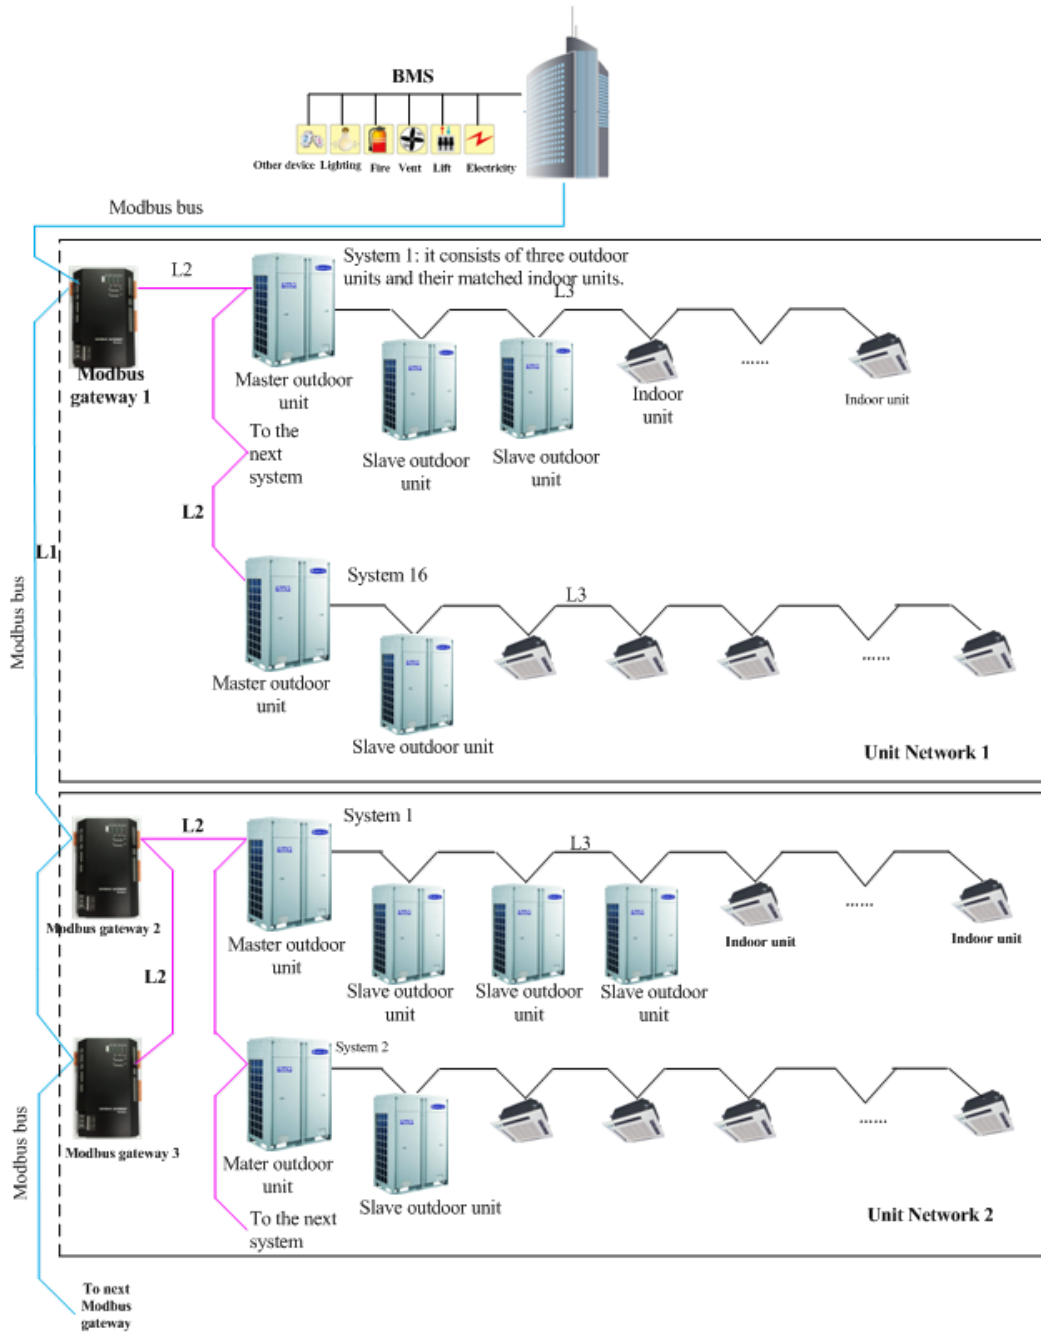

Fig.2 Detailed Network Diagram

**Notes:**

One modbus bus can support up to 255 Modbus gateways. The address of Modbus gateway is not allowed to be repeated, otherwise communication would fail.

**4. 4. MODBUS Protocol Format**

**4.1. General**

Modbus actually has become the industrial communication standard because it is not only fully opened and used widely but also simple and can be debugged flexibly. Besides, as for the communication of multiple units, it can be developed fast and also can be conveniently connected with the devices which support this protocol. There are two communication modes, RTU and ASCII. The former one is adopted for the BMS interface.

## 4.2. Protocol Interface

The protocol interface is the Modbus RTU protocol.

## 4.3. Hardware Interface

- 1) Communication Interface: RS485
- 2) Communication Mode: Baud Rate: 9600 bit/s

(In some special event, other baud rate also can be selected but the communication mode should be compatible with this protocol)

Start Bit: 1  
 Data Bit: 8  
 Check Bit: None  
 Stop Bit: 1

## 4.4. Universal Communication Frame Format of Modbus under RTU Mode

| Start Time Interval | Add. Code | Function Code | Data Area | CRC     | Stop Time Interval |
|---------------------|-----------|---------------|-----------|---------|--------------------|
| T1-T2-T3-T4         | 1 Byte    | 1 Byte        | n Bytes   | 2 Bytes | T1-T2-T3-T4        |

Under the RTU mode, there is at least 3.5ms dead time before the data transmission, which can be figured out through the adopted baud rate (like T1-T2-T3-T4 listed in the table above) and there is another 3.5 ms dead time after the transmission of the last character. After that, another set of data can be transmitted. The whole set of data should be transmitted continuously, if there is a pause more than 1.5 ms, the receiver will jump to the transmission of next set of data.

If the dead time is less than 3.5 ms, the transmission would fail as the CRC for the information combination is ineffective.

## 4.5. MODBUS Standard Protocol Format

### 4.5.1. Coil (Bit)

Table 2: Coils Data

| Add.   | Corresponding Byte | Values |
|--------|--------------------|--------|
| Bit 0  | Byte0.0            | 1      |
| Bit 1  | Byte0.1            | 0      |
| Bit 2  | Byte0.2            | 1      |
| Bit 3  | Byte0.3            | 0      |
| Bit 4  | Byte0.4            | 1      |
| Bit 5  | Byte0.5            | 0      |
| Bit 6  | Byte0.6            | 1      |
| Bit 7  | Byte0.7            | 0      |
| Bit 8  | Byte1.0            | 1      |
| Bit 9  | Byte1.1            | 0      |
| Bit 10 | Byte1.2            | 1      |
| Bit 11 | Byte1.3            | 0      |
| Bit 12 | Byte1.4            | 1      |
| Bit 13 | Byte1.5            | 0      |
| Bit 14 | Byte1.6            | 1      |

|        |         |       |
|--------|---------|-------|
| Bit 15 | Byte1.7 | 0     |
| .....  | .....   | ..... |

- 1) “Coil” indicates the data of some flag bit or failure bit etc.
- 2) The unit of date is bit and each bit has a corresponding address.
- 3) The data bit exists in the byte of the communication frame and each byte is composed of eight bits. The high-order byte is corresponding to the high-order bit, so is the low-order byte and bit. See Table 2 for more details.
- 4) The master unit can operate one bit among the communication data or multiple continuous bits at the same time.
- 5) The bit count which the master unit can read or transmit is less than Byte×8. The ineffective data bit of the last byte should be cleared when transmit or read the effective data of the communication frame. For instance, when nine “1” bits are read or transmitted, then two bytes are need, “1111 1111” and “0000 0001”. For the later byte, the ineffective bits “0” should be cleared.

#### 4.5.2. Register (Word, 16 Bits)

Table 3: Registers Data

| Add.   | Corresponding Byte | Values |
|--------|--------------------|--------|
| Word 0 | Byte 0             | AA 55  |
|        | Byte 1             |        |
| Word 1 | Byte 2             | AA 55  |
|        | Byte 3             |        |
| Word 2 | Byte 4             | 55 AA  |
|        | Byte 5             |        |
| .....  | .....              | .....  |

- 1) The unit of the register is “word “ which has a corresponding address starting from 0
- 2) When the master unit reads a word, it needs to read two bytes from the high-order eight bits to the low-order eight bits.
- 3) When the master unit transmits or read the request frame, it can transmit or read one or multiple continuous words in the data list.

#### 4.5.3. Read Multiple Coils

**Note:** It can read the coil data but not support the broadcast.

◆ **Function Code: 0x01**

Table 4: Request Frame

| Device Add. | Function Code | Starting Add. | Data Size | CRC     |
|-------------|---------------|---------------|-----------|---------|
| 1 Byte      | 1 Byte        | 2 Bytes       | 2 Bytes   | 2 Bytes |

Table 5: Response Frame

| Device Add. | Function Code | Byte Count | Effective Data | CRC     |
|-------------|---------------|------------|----------------|---------|
| 1 Byte      | 1 Byte        | 1 Byte     | n Bytes        | 2 Bytes |

- ◆ **Starting Address:** it is the starting place where to read a series of bits.
- ◆ **Data size:** It indicates the bit count.
- ◆ **Case:** Read ten bits from the coil 5 of the device 10(see Table 2 for the coil data), as follows:
- ◆ **Request Frame:** 0A(device address)01(function code)00 05(starting address)00 0A(data size)AD 77(CRC)
- ◆ **Response Frame:** 0A(device address)01(function code)02(byte count)AA 02(effective data)E3 5C(CRC) .

- ◆ The last byte is “0000 0010”, among which the ineffective bits “0” should be cleared.

#### 4.5.4. Write Multiple Coils

**Note:** The master writes coil data to the Modbus Gateway and also supports the broadcast.

- ◆ **Function Code:** 0x0F

Table 6: Request Frame

| Device Add. | Function Code | Starting Add. | Data Size | Byte Count | Effective Data | CRC     |
|-------------|---------------|---------------|-----------|------------|----------------|---------|
| 1 Byte      | 1 Byte        | 2 Bytes       | 2 Bytes   | 1 Byte     | n Bytes        | 2 Bytes |

Table 7: Response Frame

| Device Add. | Function Code | Starting Add. | Effective Data | CRC     |
|-------------|---------------|---------------|----------------|---------|
| 1 Byte      | 1 Byte        | 2 Bytes       | 2 Bytes        | 2 Bytes |

Note: The response frame has the same device address, function code, starting address and data size as the request frame.

- ◆ **Case:** set eleven consecutive bits to “1” from the device 10 and starting at the address 6, as follows:
- ◆ **Request Frame:** 0A(device address)0F(function code)00 06 (starting address)00 0B(data size)02(byte count) FF 07 (effective data)97 A0(CRC);
- ◆ **Response Frame:** 0A (device address) 0F (function code) 00 06(starting address) 00 0B (data size) F5 76(CRC);
- ◆ The last byte is “0000 0010”, among which the ineffective bits “0” should be cleared.

#### 4.5.5. Read Multiple Registers

**Note:** Read the register data but do not support the broadcast.

- ◆ **Function Code:** 0x03

Table 8: Request Frame

| Device Add. | Function Code | Starting Add. | Data Size | CRC     |
|-------------|---------------|---------------|-----------|---------|
| 1 Byte      | 1 Byte        | 2 Bytes       | 2 Bytes   | 2 Bytes |

Table 9: Response Frame

| Device Add. | Function Code | Byte Count | Effective Data | CRC     |
|-------------|---------------|------------|----------------|---------|
| 1 Byte      | 1 Byte        | 1 Byte     | n Bytes        | 2 Bytes |

- ◆ **Starting Add.:** It indicates the starting address to read the block data.
- ◆ **Data Size:** It indicates the word count with the maximum of 127 each time.
- ◆ **Case:** read two continuous words (see Table 3) from the device 10 starting at the address 1, as follows:
- ◆ **Request Frame:** 0A (device address) 03 (function code) 00 01(starting address) 00 02(data size)94 B0 (CRC);
- ◆ **Response Frame:** 0A (device address) 03 (function code) 04(byte count) AA 55 55 AA (effective data) CE 14(CRC).

#### 4.5.6. Write Multiple Registers

**Note:** Write control data from the master unit to the register and support the broadcast

- ◆ **Function Code:** 0x10

Table 10: Request Frame

| Device Add. | Function Code | Starting Add. | Data Size | Byte Count | Effective Date | CRC     |
|-------------|---------------|---------------|-----------|------------|----------------|---------|
| 1 Byte      | 1 Byte        | 2 Bytes       | 2 Bytes   | 1 Byte     | n Bytes        | 2 Bytes |

Table 11: Response Frame

| Device Add.   | Function Code | Starting Add. | Effective Data | CRC     |
|---|---------------|---------------|----------------|---------|
| 1 Byte  | 1 Byte        | 2 Bytes       | 2 Bytes        | 2 Bytes |
| Note: The response frame has the same device address, function code, starting address and data size as the request frame. |               |               |                |         |

- ◆ **Case:** Write three words (0x12, 0x23, 0x34) from the device 10 starting at the address 2, as follows:
- ◆ **Request Frame:** 0A (device address) 10 (function code) 00 02(starting address) 00 03(data size) 06 (byte count) 00 12 00 23 00 34(effective data) 15 DF (CRC)
- ◆ **Response Frame:** 0A (device address) 10 (function code) 00 02 (starting address) 00 03 (data size) 20 B3 (CRC)

#### 4.5.7. Alarm Response

**Note:** The master unit sends out a request frame, but the Modbus Gateway detects that there is some default, so an alarm response alarm is replied.

- ◆ **Function Code:** Set the highest-order bit to “1”, which is value figured out through the OR operation of the request frame’s function code and 0x80.

Communication Format of the Response Frame:

Table12: Alarm Response Frame

| Device Add. | Function Code | Alarm Code | CRC     |
|-------------|---------------|------------|---------|
| 1 Byte      | 1 Byte        | 1 Bytes    | 2 Bytes |

Description to the Alarm Codes:

Table13: Alarm Codes

| Alarm Code | Name                 | Description   |
|------------|----------------------|---|
| 0x03       | Illegal data         | The transmitted data is incorrect or beyond the data area.              |
| 0x04       | Slave device failure | There is communicating failure between the Modbus Gateway and the unit. |

- ◆ **Case:** Read 128 words from the device 10 starting at the address 0, but the data size 80 exceeds the read range of Modbus , so the replay of the alarm response frame is as follows:
- ◆ **Request Frame:** 0A (device address) 03(function code) 00 00(starting address) 00 80(data size) 45 11 (CRC);
- ◆ **Reponses Frame:** 0A (device address) 83(function code) 03(alarm code) 70 F3 (CRC).

## 5. Communication Protocol for GMV Multi VRF System

### 5.1. General

1) The BMS is available to provide the Modbus protocol interface. The long-distance monitoring system can be used to monitor the Multi VRF System(CAN Mode) or be incorporated into the BMS system. Through the long-distance monitoring PC or the BMS system, the user can take a centralized management and control to up to 256 sets of outdoor units and 1024 indoor units. It without doubt is the high-efficiency tool for the management of the intelligent air conditioners system in the modern buildings.

2) This BMS system is applicable to the Multi VRF System(CAN Mode).

3) Through this interface, it can not only realize the long-distance monitoring to the unit, including the running temperature of the unit, the status of the compressor, and the failure status but also set the unit long distantly, like temperature, running mode, on/off, mode shield, on/off shield etc.

4) In the protocol, “R” indicates “only read” and “W/R” indicates “write and read”.

### 5.2. Precautions before the Software Development to the BMS Interface for the GMV Multi VRF System

Before the software development to the provided BMB interface, please make sure the setting of the DIP switch and the wiring are correct.

#### ◆ Precautions to the Software Design:

★ (1): When there is a conflict with cooling and heating type of outdoor unit, the mode set by BMS system software is invalid. Monitoring software is suggested to indicate invalid operation.

If the outdoor unit is cooling only type, setting of heating/floor heating/heat supply/quick heating is invalid;

If the outdoor unit is heating only type, setting of cooling/dehumidifying is invalid;

If the outdoor unit is air supply type, setting of other modes is void, except air supply/fresh air.

★ (2): When there is a conflict with the mode of master indoor unit, the indoor unit mode set by BMS system software is invalid; Floor heating/heat supply/quick heating modes are handled only by the corresponding indoor units and they are invalid for other indoor units.

★ (3): When the frame type of exception response received by BMS system software is 0x04, it means there is communication malfunction between the unit and gateway.

★ (4): Energy saving process:

When “energy saving” functional is turned on, all upper limit temperature and lower limit temperature of energy saving will react.

**Setting lower limit temperature of cooling energy saving:** when “energy saving” reacts and the lower limit of energy-saving temperature is higher than the *Temperature setting* set by BMS system software, BMS system software is suggested to indicate operation failure if BMS system software sets *Temperature setting*. It is valid only when the *Temperature setting* set by BMS system software is higher than the lower limit of energy saving temperature. Lower limit temperature setting of dehumidifying energy saving, quick heating energy saving and heat supply energy saving are in a similar way.

**Setting upper limit temperature of heating energy saving:** when “energy saving” reacts and the upper limit energy-saving temperature is lower than the *Temperature setting* by BMS system software, BMS system software is suggested to indicate operation failure if BMS system software sets *Temperature setting*. It is valid only when the *Temperature setting* set by BMS system software is lower than the upper limit temperature of energy saving.

★ (5): Determine the effective range of all data sent by BMS system software to gateway.

★ (6): After de-energization and energization of gateway, prior to not receiving one frame of effective device information data, the gateway will report abnormal response 04.

★ (7): Forced mode of outdoor unit takes priority over control of BMS system software. In this case, any control of BMS system software is invalid.

★ (8): Remote lock

Under any status, setting is valid;

Under remote lock status, forced mode of outdoor unit is valid, as well as hardware resetting of indoor unit.

★ (9): ON / OFF

When unit is forcedly shutdown with power shortage (displaying malfunction code L8), start-up sent by BMS system software is invalid.

In any other case, On/Off by BMS system software is valid.

★ (10): Remote shielding of ON / OFF, shielding ON, shielding OFF

Under any status, setting is valid;

Under these three shielding status, timer of indoor unit is temporarily invalid (timer mark is not cleared), and can not be set; But timer can be cancelled by remote controller;

★ (11): 8°C heating function (i.e. absence mode)

It is valid only to set the function under heating mode. 8°C heating (absence mode) will exit automatically if switch to other modes. When 8°C heating has been set, fan speed and sleep setting are invalid;

8°C heating (i.e. absence mode) and remote shielding of temperature setting are mutually exclusive, whichever set first will prevail: that is to say, if remote shield temperature setting has been set, 8°C heating (i.e. absence mode) cannot be set; if indoor unit has been under 8°C heating (i.e. absence mode), it is invalid to set remote shield temperature setting function;

★ (12): Low temperature dehumidifying:

Setting of low temperature dehumidifying is valid only under the dehumidifying mode. Low temperature dehumidifying mode will exit automatically when switching to other mode;

Low temperature dehumidifying and remote shielding of temperature setting are mutually exclusive, the same as that of 8°C heating.

Under low temperature dehumidifying, set temperature is forced to be 12°C;

★ (13): Temperature setting

Set temperature is forced to be 8°C or 12°C when the unit is under 8°C heating or low temperature dehumidifying. In this case, Temperature setting by BMS system software is invalid.

When energy saving of indoor unit is turned on, temperature set by BMS system software will be invalid if it is beyond the limited value of energy saving (for example, the lower limit of energy saving in cooling is 20°C.

If the temperature set by BMS system software is lower than 20°C, it will be invalid); The energy saving will be of no effect temporarily, if the BMS system software sets shielding temperature. In this case, it shall response the temperature set by BMS system software.

★ (14): Shielding of temperature setting

Shielding of temperature setting is mutually exclusive with absence mode (8°C heating) and low temperature dehumidifying (whichever set first will prevail);

Energy saving will be of no effect temporarily when set temperature has been shielded;

Sleep mode will be cancelled and cannot be set when set temperature has been shielded.

★ (15): Energy saving and its limited temperature

Under fan mode, energy saving setting is invalid;

Energy saving will be of no effect temporarily when set temperature has been shielded (energy saving mark cannot be cleared);

Under any status, setting limited temperature of energy saving is valid.

★ (16): Shielding of energy saving:

Under any status, setting is valid.

★ (17): Sleep mode

The current indoor unit only has sleep mode 2. If long-distance monitoring sets sleep mode 1, mode 2 or mode 3, all of them are analyzed to be sleep mode 2, and the status responded by indoor unit is also sleep mode 2;

Sleep mode will be cancelled and can not be set when shielding temperature setting.

Sleep mode will retime when adjusting temperature setting (including BMS system software).

★ (18): Fan speed:

Under dehumidifying mode, fan speed is forced to be low fan speed. Other fan speed set by BMS system software is invalid.

If BMS system software sets the fan speed with indoor unit under turbo status or forced quiet status, the indoor unit will exit from the status; under 8°C heating, fan speed is forced to be auto. Setting other fan speed is invalid;

If the fan of indoor unit only has three kinds of fan speed, the five kinds of fan speed sent by BMS system software will be analyzed as below: low and medium-low fan speed are analyzed to be low fan speed; medium fan speed is analyzed to be medium fan speed; medium-high and high fan speed are analyzed to be

high fan speed;

★ (19): Turbo

The setting is valid only under cooling/heating mode and invalid under other modes.

Turbo cannot be set under 8°C heating;

When the indoor unit is running under quiet mode, if BMS system software sets turbo mode and it is valid, the indoor unit will enter turbo mode and exit from quiet mode;

★ (20): Quiet

Under dehumidifying/fan mode, quiet setting is invalid;

Quiet mode cannot be set under 8°C heating;

When the indoor unit is running under turbo mode, if BMS system software sets quiet mode and it is valid, the indoor unit will enter quiet mode and exit from turbo mode;

★ (21): Swing

Setting of up&down swing and left&right swing is only valid to the model with these swing ways (see indoor unit logic);

For the indoor unit without fixed angel swing function, setting (up&down, left&right) swing in position 1, position 2, position 3, position 4 and position 5 are equal to swing off; other settings are equal to swing on;

★ (22): Drying

Setting drying mode is valid only under cooling/dehumidifying mode and unit on status; it will not be cancelled in case of switching mode.

★ (23): Air exchange

Setting air exchange function by BMS system software is valid under any status;

Manual shutdown (including BMS system software) and timer off will turn off air exchange function;

★ (24): Filter cleaning reminder and elimination:

Under any status, setting is valid;

★ (25): Shielding of timer

Under any status, setting is valid;

Timer of indoor unit will be of no effect temporarily if timer is shielded (timer mark is not cleared); Timer is not displayed and cannot be set; Timer will recover after canceling shielding;

★ (26): Prohibition of auxiliary heating

Under any status, setting is valid;

Export unit doesn't have controllable auxiliary heating function and prohibition function of auxiliary heating.

### 5.3. Definition of Effective Data

The data for the Modbus communication protocol can be divided into two types: register and switching value. The former one indicates the values of temperature, valves and other continuous, multi-mode values, while the later one indicates the value which only has two status, like the temperature sensor failure (with only two options: “Yes” or “No”).

#### 1. Data and Address Distribution of the Analog Values: (Word 0 ~ Word 3458)

| Addr.    | Access Type<br>R: only read<br>W/R: write/read | Data Meaning                                   | Range   | Accuracy | Unit | Data Type (Actual Value) | Pay special attention to the data marked with ★(see section 5.2) | Remarks                |

## Annex A

### A.1 CRC Calculation Method

Calculation Method of CRC: The CRC is first preloading a 16-bit register to all 1's. Then successively transact each 8-bit bytes of the message. During generation of the CRC, each 8-bit character is exclusive ORed with the register contents. Then the result is shifted in the direction of the least significant bit (LSB), with a zero filled into the most significant bit (MSB) position. The LSB is extracted and examined. If the LSB was a 1, the register is then exclusive ORed with a preset, fixed value. If the LSB was a 0, no exclusive OR takes place. This process is repeated until eight shifts have been performed. After the last (eighth) shift, the next 8-bit character is exclusive ORed with the register's current value, and the process repeats for eight more shifts as described above. The final contents of the register, after all the characters of the message have been applied, is the CRC value. During transmission and reception of data in CRC, low order byte is in the front.

### A.2 How to Calculate the CRC

- 1) Preload a 16-bit register with FFFF hex (all 1's). Call this the CRC register.
- 2) Exclusive OR the first 8-bit byte of the message with the low-order byte of the 16-bit CRC register, putting the result in the CRC registers.
- 3) Shift the CRC register one bit to the right (toward the LSB), zero-filling the MSB. Extract and examine the LSB.
- 4) (If the LSB was 0): Repeat Step 3 (another shift). (If the LSB was 1): Exclusive OR the CRC register with the polynomial value A001 (1010 0000 0000 0001).
- 5) Repeat Steps 3 and 4 until 8 shifts have been performed. When this is done, a complete 8-bit byte will have been processed.
- 6) Repeat Steps 2 and 5 to process the next 8-bit data.
- 7) The final obtained CRC register is CRC.

### A.3 CRC Example

**Parameters:** Data (starting address of the block data), Data Size (Byte count of the block data)

**Return:** CRC Calculating Result

```
uint16 CRC_Calculate(uint8 *data, uint16 dataSize)
{
    uint8 i;
    uint8 temp;
    uint16 j;
    uint16 CRCode;
    CRCode=0xffff;
    for(j=0;j<dataSize;j++){
        CRCode=CRCode^data[j];
        for( i=0; i < 8; i++){
            temp=CRCode & 0x0001;
            CRCode=(CRCode >> 1);
            if(temp ==1){
                CRCode=(CRCode^0xA001);// 0xA001 is a preset multinomial, a constant.
            }
        }
    }
    return CRCode;
}
```
